Published binary rho worker image check

2026-10-21. Source commit `9e04a19e9862945a90098f3a5b377448e29a6819`. Public ECR worker digest `sha256:a347a784935a7713b204335e8316f780a5c3209d64cc372980c1b35bee9f81ba`.

The immutable image passed 168 of 168 archived CUDA controls on an NVIDIA L4, across all 24 challenge curves, as UID/GID 10001. The nine requested binary curves each passed seven controls and emitted nonempty distinguished point output in the positive DP1 case. Exact output bytes matched the archived CPU controls. The receipt records the engine binary hash, commands, device, per-case output hashes, failures, and sandbox ID.

The bars report output bytes for one frozen positive control. They are neither campaign point rates nor comparative performance measurements. This validation does not exercise authenticated contribution, network transport, server verification, or sustained collection. The 23.18 second receipt duration is the sandbox's in-container work; provider scheduling time is outside it.

Artifacts: `l4-image-check.json` (raw receipt), `release-manifest.json`, `codebuild.json`, `manifest-object.json`, `render_image_check.py`, and this editable PDF source. The matched native L4 arithmetic benchmark is in `verification/binary-rho-profile-20261021/`.
